

# Trends in prevalence of childhood obesity and racial and ethnic disparities in California

---

JENNIFER FALBE, SCD, MPH

CAROLYN COTTERMAN, MS

JENNIFER LINCHEY, MPH

KRISTINE MADSEN, MD, MPH

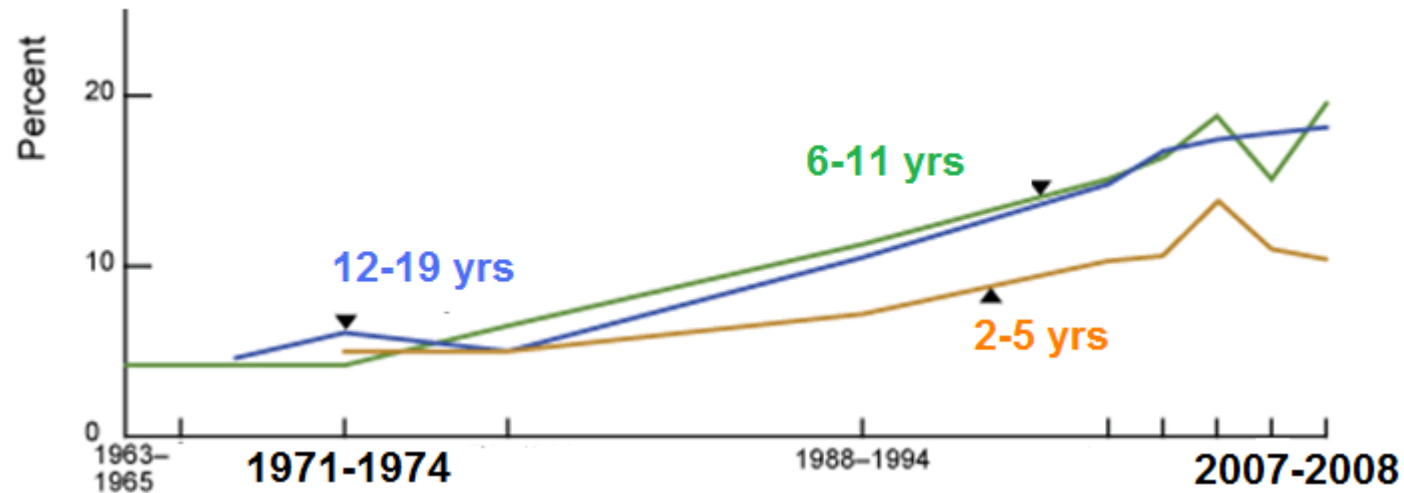

Berkeley

# Background

---

**National trends overall:** Rapid increase in prevalence of childhood obesity between 1971-2000 appears to be leveling off

*JAMA*. 2012;307(5):483-490 and CDC/NCHS, NHANES I-III, 1999-2001, 2003-2004, 2005-2006, 2007-2008; Ogden, C. L., M. D. Carroll, et al. (2014). *JAMA* 311(8): 806-814.

# Background

Prevalence of childhood overweight & obesity remains high at the national level with **large disparities** (NHANES 2011-12, 2-19 year olds)

All race/ethnicities (32%)

Non-Hispanic white boys (28%)

Hispanic boys (41%)

# Background

---

NHANES (National Health and Nutrition Examination Survey)

**Strengths:** Nationally representative, researcher measured height and weight

**Limitations:** Relatively small sample size with large SE for prevalence of high BMI

→ difficult to detect differences in trends by race

# Background

---

## DISPARITIES MATTER, BUT SO DO DISPARITIES IN TRENDS

- Are some groups being reached by/responding to interventions more slowly or later in time?
- What is our progress thus far toward meeting the *Healthy People 2020* goal, to “achieve health equity and eliminate health disparities?”
- Need to look beyond NHANES and use larger datasets
- Several studies using other datasets have indicated growing disparities over time

# Objective

---

To examine **trends** in high BMI among children in California from 2003-2012, by race/ethnicity, using the state's school-based Fitnessgram dataset

# Objective

**Obesity trends:** Prevalence peaked, declined, and/or plateaued between 2003 and 2012

- 3 high BMI cut-offs:
  - BMI  $\geq 85^{\text{th}}$  %tile (CDC definition of “overweight or obese”)
  - BMI  $\geq 95^{\text{th}}$  %tile (CDC definition of “obese”)
  - BMI  $\geq 97^{\text{th}}$  %tile
    - Added health risks
    - Previously examined in NHANES

# Why California (CA)?

- Annual BMI screening of 5<sup>th</sup>, 7<sup>th</sup>, & 9<sup>th</sup> graders in public schools as part of FitnessGram
- Home to 13% of children in the U.S.
- Includes understudied Asian and American Indian youth
- Home to considerable proportions of the country's racial/ethnic minority youth:
  - >25% of Hispanic youth
  - ~30% of Asian youth
  - >10% of American Indian youth
- Ample power to examine differences in trends by race/ethnicity
- Highest Medicaid & CHIP spending

# FitnessGram

---

## **Fitnessgram:** 6 fitness areas established by Cooper Institute

- Aerobic capacity
- Abdominal strength & endurance
- Upper body strength & endurance
- **Body composition**
- Trunk extensor strength & flexibility
- Flexibility

Reported to CA Dept of Education (CDE)

<http://www.cde.ca.gov/ta/tg/pf/>

# Methods

---

## Repeated cross-sectional data

### Data sources

- Student records from CDE: gender, grade, age in months, height, weight, and race/ethnicity
  - African American, American Indian/Alaskan Native, Asian [including Filipino and Pacific Islander], Hispanic/Latino, and white not of Hispanic origin
- Enrollment data from CDE website

# Methods

---

## Population

- 13,945,046 student records from 2003-2012, representing 93.5% of 5<sup>th</sup>, 7<sup>th</sup>, and 9<sup>th</sup> graders enrolled

## Exclusions

- 17% of records had missing/invalid/implausible data on height, weight, age, BMI, and/or BMI z-scores
- Students with unknown, missing, or multiple race designations

Analytic sample: 11, 624, 865 (78% of total enrollment from 2003-2012)

## Recoding of race/ethnicity

- In 2011,  $\geq 2$  races (4% in 2011-2012)
- $\sim 1/2$  had a prior single race designation, to which the record was assigned
- Beginning in 2008, CDE student records could be linked using a random id

# Statistical Analysis

---

Sex- & race-specific logistic regression models adjusting for age

Robust SEs: clustering within school district

# Statistical Analysis

---

**Peaks (increases)** between 2003-2012

“Peak year”: year prevalence was highest

To identify significant increases in prevalence (i.e., peaks), year was a categorical predictor with 2003 as reference

Significant if OR comparing peak prevalence to that in 2003 was significantly  $>1.0$  ( $P < 0.05$ )

# Statistical Analysis

---

**Decline or Plateau** from peak year to 2012

Separate logistic regression models with peak year as reference were used to determine if the prevalence **declined** or plateaued from the peak year to 2012

**“Plateau”**: Pattern of change wherein prevalence peaked after 2003 but did not decline thereafter

# Results: Race/ethnicity of sample

---

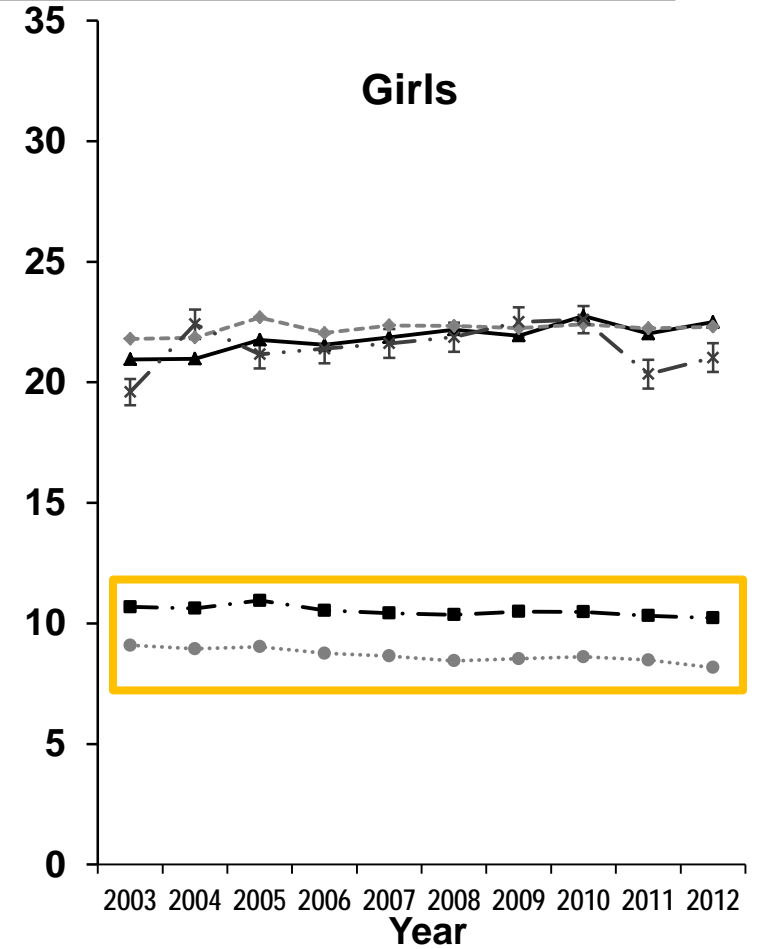

# Results: BMI $\geq$ 95<sup>th</sup> %tile

# Results: BMI $\geq 95^{\text{th}}$ %tile

# Results: BMI $\geq 95^{\text{th}}$ %tile

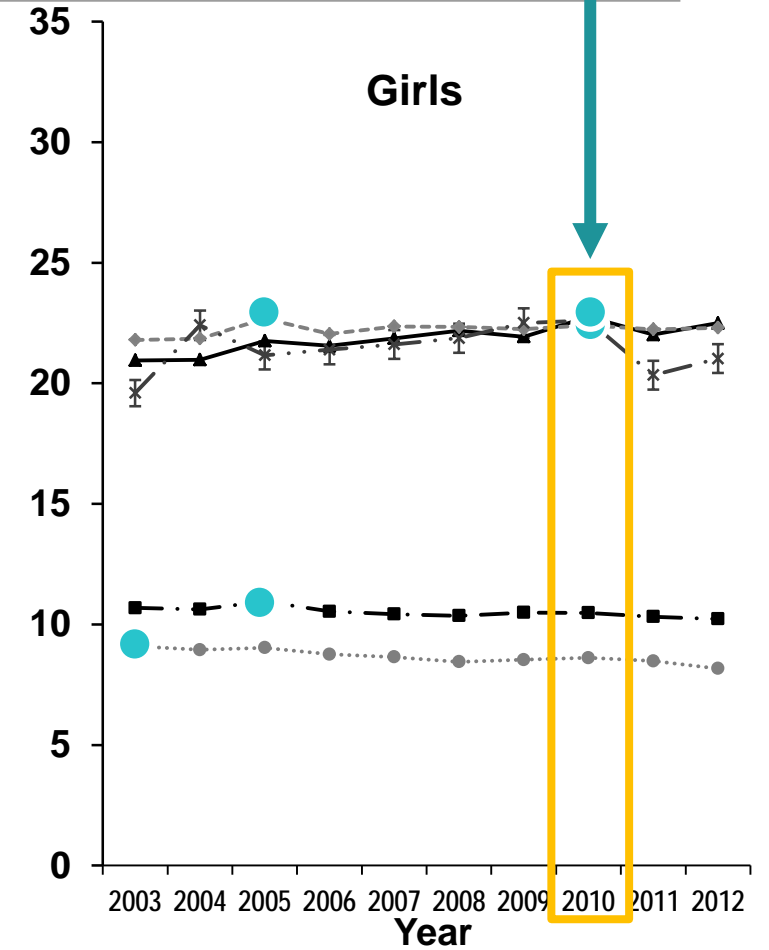

# Results: BMI $\geq 95^{\text{th}}$ %tile

# Results: Trends by cut-points (BMI $\geq$ 85<sup>th</sup>, 95<sup>th</sup>, & 97<sup>th</sup> %tiles)

---

The magnitude of proportional increases from 2003-peak year (prevalence increase  $\div$  prevalence in 2003) rose with higher BMI cut-points (except for Asians)

E.g., for American Indian girls...

BMI cut-point	Proportional increase
BMI $\geq$ 85 <sup>th</sup> %tile	7.5%
BMI $\geq$ 95 <sup>th</sup> %tile	15.4%
BMI $\geq$ 97 <sup>th</sup> %tile	21.3%

Highest proportional increases for all cut-points:

- American Indian > African American > Hispanic

## Results for trends in obesity prevalence 2003-2012

---

Higher increases in prevalence for American Indian, African American, and Hispanic compared to White and Asian youth

American Indian and African American youth had later peaks

While most groups declined in obesity prevalence after peak year, American Indian youth and African American girls plateaued

2012 prevalence remained > 2003 prevalence for American Indian and African American youth and Hispanic girls

# Discussion

---

- No single group had a steady increase in obesity through 2012, unlike in a previous analysis of CA (Madsen KA, 2010, Pediatrics)
- Some improved: White & Asian youth and Hispanic boys had a 2012 prevalence that declined to  $\leq$  2003 levels
- Disparities have continued to widen, with less favorable trends for American Indian and African American youth and Hispanic girls
- Larger proportional increases for higher BMI cut-points  $\rightarrow$  concerning given added risks & "costs"

# Discussion

---

## Strengths

- Large dataset (>11 million records)
- Inclusion of understudied groups
- Representative of CA public school children

## Limitations

- Uncertainty about data collection across schools
- Single category for Asian and PI may mask variation
- Change in 2011 to allow  $\geq 2$  races

# Discussion

---

**Call to action for policies and programs to accelerate progress for minority youth in CA**

# Linear trends

---

## Boys

- + trend for American Indian boys
- - trend for Hispanic, Asian, and White

## Girls

- + African American and Hispanic girls
- - For Asian

African American, Hispanic, and American Indian girls and boys had higher slopes than their white counterparts (Ps for interaction  $<0.05$ )
